

SquareOps: Technical SEO & Authority Strategy

Part 1 - Diagnose one live page url - <https://squareops.com/vapt-services/>

Based on the data given in the table, we see that the webpage SERP position is 42.9 which is somewhere between page 4 and 5. Also, 1525 impressions with 0 clicks in 6 months confirms the fact that barely anyone is able to find this page even with long tail keywords.

To rule out certain tech and page performance related issues, we ran a check of the webpage with Pagespeed insights and Ahrefs. The page didn't have any links to 404 or error pages and the page performance is also acceptable for desktop and mobile devices.

What's holding this page back: the top three issues

Issue 1 - Product positioning mismatch

I went through multiple pages on the website and found that the page is not properly optimized for the keyword "vapt services".

The majority of the site is positioned as a DevOps/cloud/compliance - service provider. I took help of the AI to find out the use of certain industry specific keywords on various pages on the site like "pentesting", "vulnerability assessment" but most of it is mentioned as a single line item on other pages of the site.

The term "VAPT services" is making SquareOps compete with specialized companies that are offering this service separately. Companies that offer offensive security auditing and services. Our page doesn't clearly indicate whether the company is offering standalone VAPT services.

Issue 2 - Standard content but no specifics:

The site mentions the standard OWASP Top 10 list, the six-step process graphic, and the standard FAQ but they are likely the same copy text for every other pentest webpage. A page that reads similar to a competitor is a strong reason for Google to not prefer it over their content.

The page majorly lacks in sample reports, no VAPT-specific client story and no details about pricing. Few links found near the end of page like (<https://squareops.com/case-studies/fintech-nbfc-workload-migration-gcp-to-aws/>) talks about cloud infra migration which is good for other services that SquareOps provides but not helpful for VAPT service. So the proof exists but not about VAPT.

Issue 3 - Domain authority:

The backlinks to this webpage are random technical sources rather than a genuine, authoritative endorsement(attached PDF). The page is internally orphaned from the high-performing internal pages like Cloud Security, DevSecOps, and Managed Kubernetes

content.

What I would change in the first two weeks

Assuming that squareops doesn't have a unique proposition, it is difficult to compete on generic terms like "VAPT services" & "pentesting services". Instead, I would recommend repositioning the page around Specialized penetration testing for cloud infra".

1. **Title tag (currently "VAPT Services: Vulnerability & Pen Testing | SquareOps"):**
"Cloud & Kubernetes Penetration Testing | OSCP-Certified | SquareOps"
2. **Page structure changes:**
 - a. Removing/moving the standard questions like "What is VAPT?" below the fold.
 - b. Moving up the certifications section and adding subheadings for long-tail keywords like "Kubernetes vulnerability security assessment", "ISO 27001 certified penetration testing".
3. **Add pricing page:**

Adding an indicative price range instead of showing the consultation modal.

 - a. The enterprise sales section under pricing should have a CTA with "Schedule a demo" or contact sales.

Expected results, what to measure and when

By 2-4 weeks - we should look at Google search console and google analytics for 2 specific trends:

1. An increase of total impressions month over month from current baseline.
2. Gather data from google analytics to look for a shift in our search terms. Today, the page only shows up for generic VAPT. If our suggestions above are working, highly targeted phrases like 'AWS penetration testing,' 'Kubernetes security assessment,' and 'penetration testing for cloud infra' will begin appearing in the reports.

By 6-8 weeks - we need to check whether the impressions are leading to organic clicks and start analyzing the bounce rate and page engagement data.

Our target should be to start appearing in top 15-20 positions for the keywords we have added in our titles and heading that have specialized cloud terms. If we are not moving towards these targets then we may have to revisit our SEO strategy.

By the end of 3 months - we need to evaluate whether the improvement in impressions and clicks leading to a potential leads for conversion. The area of VAPT in cloud infra is very specific so our target should be to generate 2 to 3 qualified inquiries per month from buyers for scheduling a consultation or demo.

Part 2 - Authority and visibility

Assuming we have a budget Rs.1,00,000 per month for six months to build authority for commercial queries like "kubernetes managed services", "AWS managed services India" and "AWS managed services USA".

We would like to break down the budget into multiple buckets as below:

1. **Original studies & benchmark reports** - A major part of the budget would go into getting technical writers for publishing benchmark articles with cost and service comparisons for cloud managed services.(40-45k/month estimated by AI)
2. **Getting named in existing lists of top ranked articles** - Outreach to the publishers that have published blogs and articles which are already ranked and get quoted for certain phrases ("top Kubernetes consulting partners," "best AWS MSPs"). (20-25k/month estimated by AI)
3. **AI result measurement** - tracking rank and suggestions for AEO from premium or freemium tools like profound or scrunch. These tools provide ways to run fixed AI-prompt that tests every month to check how SquareOps appears in AI summaries. (**average \$100-\$150 subscription**)

We can keep some budget in reserve, measure the above buckets consistently and divert the spare budget as needed.

What I would deliberately not spend on, and why

1. **Paid links** - Cheap backlinks are a dangerous liability and at times backfire. We have a report that shows VAPT service pages having backlinks from low domain authority websites.
2. **High-volume informational content** ("what is Kubernetes") experts/buyers won't look for informational content.
3. **Paid search for keywords** - Most industry specific queries we tested had AI Overviews. These terms get answered without a click now. So this is something one shouldn't pay for.

Part 3 - Sample article

How do I choose a Kubernetes managed service provider?

Most teams start by comparing size or price. The better question is: what can go wrong in your setup, and will this provider take care of it? A team running a simple stateless app has different needs than a team running regulated, stateful workloads. You should choose the provider that covers your risks, not the one with the longest feature list. Below are the six things that matter most:

1. **Look for deep skill on your cloud, not a little of every cloud** - "Multi-cloud" often means average everywhere. If you run on AWS, you should pick an [AWS Advanced Tier partner with real EKS experience](#). They will handle Karpenter, Graviton, and Spot pricing much better than a

generalist. The same logic applies to GKE and AKS. Ask them to show past work on your cloud, at your scale.

2. Check if they run production, or only set it up - Anyone can create a cluster. The real work comes after: version upgrades, autoscaling, disaster recovery that has been tested, and someone awake at 3 a.m. when a node fails. Here is a simple test you can use: ask how they would handle a cluster that is two versions behind and close to entering extended support. A real [managed Kubernetes operation](#) will show you an upgrade runbook and a rollback plan. A setup-only shop will let it slip and hand you the 6x bill. You should also ask where their engineers sit during your night hours. 24/7 on paper is not always 24/7 in practice.

3. Ask if security is included, or an add-on - If you handle regulated data, ask what they set up by default: RBAC, network policies, pod security, encryption, CIS benchmarks, image scanning. If they [harden clusters by default](#), security is part of their process. If it costs extra, it is an afterthought. A provider serving SOC 2 or PCI-DSS workloads should show you its compliance record without being asked twice.

4. Make sure you will own your infrastructure, not them - Lock-in is not only a cloud problem. It can be a provider problem too. A good partner builds on standard Kubernetes and infrastructure-as-code that stays with you. You should be able to leave tomorrow and keep everything. If leaving means untangling their private tooling, treat that as a warning sign.

5. Ask them to show you cost per workload, not just run the cluster - Kubernetes bills hide the details. Node costs never show which team is spending the money. A provider who ignores cost will happily run an oversized cluster forever. A good one brings [per-workload cost visibility and continuous rightsizing](#), so your spend stays flat as you grow.

6. Be honest about whether you need one at all - A small stateless workload may run fine on the managed control plane plus Fargate. A strong in-house platform team may only need advice, not full management. A managed provider makes sense when Kubernetes is critical to your business and your team is stretched. Not before.

7. How to decide - skip the sales deck. Ask for two references at your scale on your cloud, a scoped assessment of your current setup, and SLAs in writing. The provider willing to be measured on response times and cost results is usually the one worth hiring.
